# A Calculation Program for Geoid Undulations Using Orthogonal Polynomials 

Fuat BASCIFTCI and Cevat INAL, Turkey

Key Words: Geoid, GPS, Ellipsoidal Height, Orthometric Height

## SUMMARY:

In recent years, the use of GPS (Global Positioning System) for precise point positioning in various applications in Turkey as in other countries has caused serious changes. Three dimensional coordinates which are obtained easily, rapidly and precisely by GPS have been used widespread in several applications such as drawing large scale maps and data collection for geographical information system. The latitude and the longitude obtained by GPS are used directly or after they are transformed, but ellipsoidal heights can't be used in applications. In order to transform the ellipsoidal heights to orthometric heights used in applications, the geoid undulations that have adequate accuracy must be known.
In this study, a computer program called TRANSFORMER in DELPHI language was written for the calculation of geoid undulations according to the fiducial sites by orthogonal polynomials. By this program, an appropriate surface was fitted using the undulations for fiducial sites of which appropriateness of $\mathrm{x}, \mathrm{y}$ coordinates was proved and geoid undulations are known.

# A Calculation Program for Geoid Undulations Using Orthogonal Polynomials 

Fuat BASCIFTCI and Cevat INAL, Turkey

## 1. INTRODUCTION

The three dimensional information has been obtained by GPS. Height is the third dimension among these dimensions. Today, when we talk about the height of a point, the vertical distance of the point from the sea level is understood. So, the mean sea level must be determined firstly. In our country, the mean sea level was measured at the tide gauge site of Antalya for 22 years, and the country leveling network was coded according to these results (Arbey, 1988; Inal, 1996). In many countries, the spot elevations were determined according to the mean sea level. The mean sea level constitutes a sufficient reference surface for the construction of height unity in a country. If the unity wanted for the heights all over the earth, the geoid must be taken into account as a reference surface. Geoid is the most important reference surface for heights, and it constitutes a leveling reference surface for heights that best fixes at the mean sea level (Torge, 1980).

Figure 1. The relation between the mean sea level and geoid
However, today, the height from the geoid and the mean sea level are assumed as the same in many engineering applications. Because of this, we can define the geoid as the best matched potential surface at the mean sea level (İnal, 1996).

## 2. THE DETERMINATION OF THE GEOID UNDULATIONS BY GPS/LEVELING

The latitude, longitude and ellipsoidal heights are determined in a global geocentric coordinate system for every points on earth by GPS (Global Positioning System). The orthometric heights of points must be used in the engineering works and for drawing maps. The orthometric heights are determined classically by geometric levelling measurements which depend on the National Vertical Control Network. The appropriate geoid models must be determined for transforming the orthometric heights directly from ellipsoidal heights obtained by GPS (Kılıçoğlu, 2002).

The undulation of the geoid as seen in Figure 2 is calculated by the following equation (Liddle, 1989; Ollikainen, 1997).

$$
\begin{equation*}
\mathrm{N}=\mathrm{h}-\mathrm{H} \tag{1}
\end{equation*}
$$

where N : the undulation of the geoid, h : ellipsoidal height, H : orthometric height.

Figure 2 The relation between orthometric and ellipsoidal heights. (Zhan-Ji 1998)

## 3. THE INTERPOLATION BY POLYNOMIAL SURFACES

One of the most common techniques used for the determination of geoid undulations is to fit an analytical surface which both values of ellipsoidal and orthometric heights are known and to the best shaped points of the geoid are benefited. The mathematical model that is obtained by the surface-fitting is used to find out the value for the middle points of the geoid undulation. The fact must not be forgotten that only the undulation of the geoid values of the middle points can be calculated by the surface-fitting model. The calculated values are used for the orthometric height values. This method is similar to the astrogeodetic method. In both methods; except the errors due to observation, the highest accuracy is obtained from the applications using very close stations in where the area of the geoid is smooth (King et al. 1985).

The interpolation technique with the polynomial surfaces is the most common technique used for surface modeling. The main aim of this technique is to model the working area by one function. The basic feature of this technique is to produce fixed coefficients by using the fiducial points of which values are known to form the model surface and to find out unknown dimensions by using the known dimensions of the new points with the fixed coefficients (İnal and Yiğit, 2004).

For the surface fitting, the following equation can be used:
$N(x, y)=\sum_{k=0}^{n} \sum_{\substack{j=k-i \\ i=0}}^{k} a_{i j} x^{i} y^{j}$
where,
aij : Unknown coefficient of polynomial,
n : The degree of the surface $(1,2,3)$,
$\mathrm{x}, \mathrm{y}$ : The plane coordinated of the points,
$\mathrm{i}, \mathrm{j}:(\mathrm{x}, \mathrm{y})$ The positive integer of the bases of the coordinates (Petrie and Kennie, 1987).
In equation (2), when the degree of the polynomial is chosen as $n=1$, it means the surface is linear, when it's chosen as $n=2$, the surface is quadratic, when it's chosen as $n=3$ the surface is called as cubic.

If the amount of fiducial sites is more than unknown numbers, the $\mathrm{a}_{\mathrm{ij}}$ coefficients are calculated by adjustment using the least squares method. A; is the coefficient matrix, L; is the value which shows the undulation of fiducial sites; and then the following equations can be written as those followings:

$$
\begin{align*}
& N=A^{T} A \\
& n=A^{T} L  \tag{3}\\
& x=N^{-1} n
\end{align*}
$$

The following equations can be written according to the surface degree in interpolation as polynomials;

$$
\begin{array}{lc}
N(x, y)=a_{0}+a_{1} y+a_{2} x & n=1 \\
N(x, y)=a_{0}+a_{1} y+a_{2} x+a_{3} x^{2}+a_{4} x y+a_{5} y^{2} & n=2  \tag{4}\\
N(x, y)=a_{0}+a_{1} y+a_{2} x+a_{3} x^{2}+a_{4} x y+a_{5} y^{2}+a_{6} x^{3}+a_{7} x^{2} y+a_{8} x y^{2}+a_{9} y^{3} & n=3
\end{array}
$$

By this method, if the surface degree is 1 , at least 3 , if the surface degree is 2 , at least 6 , if the surface degree is 3 , at least 10 fiducial sites are needed (İnal, 1996).

## 4. THE DETERMINATION OF THE OUTLIER POINTS

The outlier points among fiducial sites which are used in the calculation of the transformation parameters must be cleaned. For this, surface function is determined firstly. $V_{i}$ difference is calculated between the known geoid undulations and geoid undulations obtained using the function below:
$m_{0}=\sqrt{\frac{[V V]}{P}}$
P shows the number of the fiducial sites used in transformation. The test size is determined by using the equation below:

$$
\begin{equation*}
\mathrm{T}_{\mathrm{i}}=\frac{\left|\mathrm{v}_{\mathrm{i}}\right|}{\mathrm{m}_{0}} \tag{6}
\end{equation*}
$$

The determined test sizes are compared with the limit value with the error probability $\alpha=0.05$ in equation (7).
$\mathrm{C}=\sqrt{(\mathrm{p}-1)^{*\left(1-\left(\frac{\alpha}{\mathrm{p}}\right)^{\left(\frac{1}{\mathrm{p}-2}\right)}\right)}}$
The biggest $T_{i}$ value which is bigger than $C$ limit value is accepted for the determination of outlier point. The operations are repeated after this point was omitted. The same operation is carried out several times until there is no outlier point in the point group (Bektaş and Doğan, 1998).

## 5. THE INTRODUCTION OF THE DEVELOPED COMPUTER PROGRAM

Programming the transformation in one dimension (the calculation of the geoid undulations by using the orthogonal polynomials), in two dimension and in three dimension coordinate systems are performed by the developed program, transformer. DELPHI programming language was used while developing the program since its visual sides are very strong and the process can be performed as functions, thus transformer can be used in all PC's because of its installation feature.

The control points for the geoid undulations can be calculated by orthogonal polynomials in which the fiducial sites are benefited by transformer program. The program's interface for the one dimensional transformation is seen in figure 3.

Figure 3. The program's interface for the one dimensional transformation
The method and the correlation can be seen together after the desired method is chosen (Figure 4).

Figure 4. Interfaces for the beginning stages of the program for linear, quadratic, cubic methods.

By clicking on calculate button in these interfaces, the view of the liner method at Figure 5, the quadratic method at Figure 6, the cubic method at Figure 7 can be seen on the screen.

Figure 5. The view of the linear method.

### 5.1. The File Structure

The point entrances in transformer program can be done either manually, or in the form of a text file in MS Windows. Two text files belong to fiducial sites and control points must be formed. The text file for the fiducial sites includes coordinates of y , x and the geoid undulation (Figure 8), and the file for control points includes y and x coordinates of the points (Figure 9).

## 6. APPLICATION

64 points with Gauss-Kruger coordinates and known geoid undulations were utilized in the work area. Among them, 20 points in an appropriate distribution were taken as the fiducial sites and the other remaining 44 points were chosen as control points (Figure 10). The geoid undulations at the 44 control points were calculated by the transformer program.

The outlier measurement test was applied to all orthogonal polynomial surfaces used. According to the test result at the fiducial sites in liner method, the point of 217 was determined as outlier fiducial and the rest of 19 fiducial points and unknown surfaces were reanalyzed. The 20 fiducial sites were found matched to the reference surface according to the quadratic and cubic method. For the 44 control points that were determined by the help of unknowns, the geoid undulations found by GPS/Leveling (Figure11), and the undulation differences are shown in table 2.

Figure 11. The geoid undulations at the control points.

Integrating Generations
FIG Working Week 2008
Stockholm, Sweden 14-19 June 2008
equation (5) which were determined by the deviations from the fiducial sites of the surface point. The root mean square errors are shown at table 3 .

Table 3. The root mean square errors determined from the interpolation of the orthogonal polynomials.

|  | Liner <br> $\mathbf{m}_{0}(\mathbf{c m})$ | Quadratic <br> $\mathbf{m}_{0}(\mathbf{c m})$ | Cubic <br> $\mathbf{m}_{0}(\mathbf{c m})$ |
| :--- | :--- | :--- | :--- |
| Step 1 | $\pm 6.36$ | $\pm 6.11$ | $\pm 3.13$ |
| Step 2 | $\pm 4.86$ |  |  |

## 7. CONCLUSION

The degree of the surface polynomial that were used for the working area cannot be estimated previously. To determine this, the degree of the surface polynomial can be determined by statistical analysis of the adjusted results starting from the first degree polynomial. The last variance value gets smaller when the polynomial degree increases. The one lower degree than the polynomial degree of the latest variance when it is started to increase is accepted as the most appropriate degree.

In this study, a program called transformer was developed in the Delphi to compute the geoid undulations by orthogonal polynomials. The x , y coordinates of the fiducial sites proved in matching and transformation parameters using geoid undulations can be determined by this program. The geoid undulations of the control points at the test area were calculated by the developed program, and the calculated values and the known points of GPS/Leveling values were compared.

The results of the comparison can be summarized as followings;

- The difference between GPS/Leveling and the geoid undulations determined by the linear method changes between 8.39 and 13.24 cm , and the root mean square error of this case is $\left(\mathrm{m}_{0}\right) \pm 4.86 \mathrm{~cm}$,
- The difference between GPS/Leveling and the geoid undulations determined by the quadratic method changes between -11.35 and 9.54 cm and the root mean square error for this case is $\left(m_{0}\right) \pm 6.11 \mathrm{~cm}$,
- The difference between GPS/Leveling and the geoid undulations determined by the cubic method changes between -5.79 cm and 8.64 cm and the root mean square error for this case is $\left(\mathrm{m}_{0}\right) \pm 3.13 \mathrm{~cm}$,
- The cubic method shows a good approache to the determined values by GPS/Leveling at the work area.

## BIOGRAPHICAL NOTES

Fuat Basciftci, born in 1978. I was graduated from Selcuk University, Engineering and Architecture Faculty, Geodesy and Photogrammetry Engineering Department in 2001. I started working as a lecturer at Selcuk University, Kadinhani Faik İçil Vocational School of Higher Education, Mapping-Cadastre Programme in the same year. I graduated from the Master Education in 2008. My interests are geoid determination, transformations and GPS.
